

ASSIGNMENT 0

Name: Chandrima Bhattacharya

Course No: CS 5785

Question 1:

Find and download the Iris Flowers dataset from the UC Irvine Machine Learning datasets archive at <http://archive.ics.uci.edu/ml/datasets.html>. How many features/attributes are there per sample? How many different species are there, and how many samples of each species did Anderson record?

Iris.name present in the UCI ML dataset archive [1] describes the Iris sample. There are 4 numerical attributes present along with the Class. The attributes include Sepal Length, Sepal Width, Petal Length and Petal Width.

The Class mentions 3 species present for the Iris Dataset. The species are:

- Iris Setosa
- Iris Versicolour
- Iris Virginica

For each species, Anderson recorded 50 samples. Hence, we have 4 features defining 3 classes and a total sample size of 150 data.

Question 2:

Figure out how to parse the dataset you downloaded. Load the samples into an $N \times p$ array, where N is the number of samples and p is the number of attributes per sample. Additionally, create a N -dimensional vector containing each sample's label (species).

Initially, I saved the data in txt format (irisData.txt), which I converted into csv file by using Microsoft Excel (Book1.csv). Microsoft Excel gives option for viewing comma delimited document in matrix form, hence I used the following. After that I used Panda [2] DataFrame [3] for viewing the sample as $N \times p$ matrix. Also, I used set_option [4] to set the option to view the entire data for better understanding. The following code was used to do it:

```
import pandas as pd
df = pandas.read_csv(r"C:\Users\Chandrima\Desktop\Book1.csv")
pd.set_option('display.max_rows', 151)
print (df)
```

Question 3:

To visualize this dataset, we would have to build a p-dimensional scatterplot. Unfortunately, we only have 2D displays so we must reduce the dataset's dimensionality. The easiest way to view the set is to plot two attributes of the data against one another and repeat for each pair of attributes. Create every possible scatterplot from all pairs of two attributes. (For example, one scatterplot would graph petal length vs sepal width, another would graph petal length vs. sepal length, and so on). Within each scatterplot, the color of each dot should correspond with the sample species.

Initially, I used matplotlib [5] and seaborn [6] for data visualization. The Implot [7] function in seaborn have a feature called hue which helps us differentiate the color based on classes. For viewing any 2 features I used the following code below:

```
import matplotlib.pyplot as plt
import seaborn as sns
import pandas as pd
df = pd.read_csv(r"C:\Users\Chandrima\Desktop\Book1.csv")
sns.lmplot(x="SepalLength", y="SepalWidth", data=df, hue='Species', fit_reg=False)
plt.show()
```

For visualizing all the combinations of 2 features (a 4P_2 combination), I used multi plot grid feature of seaborn called the PairGrid [8] to find all the pairs possible and visualize them. The code for the multi plot visualization is below:

```
import seaborn as sns
import matplotlib.pyplot as plt
df = pd.read_csv(r"C:\Users\Chandrima\Desktop\Book1.csv")
irisplot = sns.PairGrid(df, hue="Species")
irisplot.map(plt.scatter);
irisplot.savefig ("irisPlot.png")
irisplot.fig.subplots_adjust(top=0.9)
irisplot.fig.suptitle('Iris Dataset Visualization', fontsize=16)
```

Note: Code and visualization is attached after Reference page.
